

BilisOps Chat

Multichannel Customer Service Workspace for E-commerce Sellers

App Category: Customer Service

This document is submitted as an attachment to our developer application. It introduces the product, explains exactly how the app uses the platform's open APIs under the Customer Service category, and summarizes our data-protection practices.

Application name	BilisOps Chat
Developer / operator	BilisOps
App type	Web application (seller-facing SaaS)
Primary market	Philippines and Southeast Asia (SME sellers)
Contact	bilisops.app@gmail.com

Prepared July 2026

1. What BilisOps Chat does

Sellers in Southeast Asia typically sell on several marketplaces at once. Every platform has its own seller-chat screen, so customer-service agents juggle multiple browser tabs, reply slowly, and miss buyer messages — which hurts response-rate metrics and costs sales.

BilisOps Chat solves this with one unified customer-service inbox: buyer messages from each store the seller has authorized arrive in a single queue, agents reply from one screen, and every reply is sent back through the platform's official message API.

2. Core features (Customer Service)

- **Unified inbox** — all authorized stores in one conversation queue with platform labels
- **Quick replies** — canned response templates with variables, inserted in one click
- **Auto-reply rules** — welcome and off-hours messages within each platform's messaging policy
- **AI-assisted drafts** — agents may generate a suggested reply; a human reviews before sending
- **Order context** — read-only order status shown beside the chat to answer "where is my order?"
- **Review & after-sale handling** — reviews, refund and cancellation inquiries worked as tickets
- **Sensitive-word guard** — outgoing messages are blocked if they contain policy-risk phrases
- **Service analytics** — response time, response rate, and resolution metrics per agent and store

3. Product interface

Illustration of the unified inbox: conversations from Shopee, Lazada, TikTok Shop and Messenger in one queue.

4. Terminology mapping (multi-platform normalization)

Our adapter layer normalizes each platform's data model into one canonical structure, respecting each platform's own concepts — e.g. a buyer is a "user" (im_user_id) on TikTok Shop, a "buyer" (buyer_user_id) on Shopee, a chat is a "session" on Lazada IM, and orders are referenced by order_sn on Shopee versus order_id elsewhere. This keeps our API usage precise and minimal on every platform.

5. How the app uses the platform Open API

We request only the scopes needed for customer service. All access is per-store, granted by the seller through the platform's official authorization flow, and revocable by the seller at any time.

API / capability	How we use it	Access
Message push / webhook	Receive new buyer chat messages for authorized stores in real time	Receive only
Send message API	Deliver the agent's reply back to the buyer in the same conversation	Send on behalf of seller
Conversation / message list	Load recent history so agents see conversation context	Read only
Order status (basic)	Show the order a buyer is asking about beside the chat	Read only, seller's own orders
Shop / seller profile	Display the authorized store's name in the workspace	Read only

We do NOT request: order creation or modification, price or stock changes, finance/settlement data, or marketing audience data.

6. Integration flow

7. Data protection and compliance

- **Official authorization only** — sellers connect stores via the platform's OAuth flow; we never ask for marketplace passwords
- **Signed webhooks** — incoming pushes are verified with the platform's signature scheme (HMAC) before processing
- **Encrypted secrets** — access tokens are stored encrypted and never exposed to the browser
- **Strict tenant isolation** — every record is scoped to the owning seller; one seller can never read another's data
- **Purpose limitation** — buyer data is used only to display and answer that seller's conversations — never sold, shared, or used for advertising
- **Human oversight of AI** — AI-suggested replies are drafts; an agent reviews and sends, and the AI uses only the seller's own knowledge base
- **Revocation & deletion** — sellers can revoke a store at any time; its synced data is deleted within 30 days
- **Policy compliance** — auto-messages follow each platform's messaging windows and anti-spam rules; a sensitive-word filter blocks policy-risk replies

8. Technical summary

Frontend	React (Vite) web application
Backend	Node.js (Express) REST API with per-platform adapter layer
AI assistance	Anthropic Claude API for human-reviewed reply drafts
Hosting	Cloud-hosted; HTTPS everywhere

9. Why approve this application

Faster, better customer service directly improves the platform's own buyer experience: quicker replies, higher seller response-rate metrics, fewer missed chats, and better-handled after-sale issues. BilisOps Chat requests the minimum scopes required to deliver that, under the seller's explicit authorization.

We are happy to provide additional documentation, screenshots, or a live demo on request.
